

## Homework

due on Wednesday, December 10

Read carefully Chapter 7, sections 34, 37, 39, 40 of Hartshorne's book. Solve the following problems:

**Problem 1.** Consider 4 circles  $S_1, S_2, S_3, S_4$ . Suppose that  $S_1, S_2$  intersect at  $A_1$  and  $A_2$ , circles  $S_2, S_3$  intersect at  $B_1$  and  $B_2$ , circles  $S_3, S_4$  intersect at  $C_1$  and  $C_2$ , and circles  $S_4, S_1$  intersect at  $D_1$  and  $D_2$ . Suppose furthermore that the points  $A_1, B_1, C_1, D_1$  are on a circle  $S$  (or on a line). Prove that the points  $A_2, B_2, C_2, D_2$  are also on a circle (or on a line).

Hint: Consider a circular inversion with center  $A_1$  (in any circle with center  $A_1$ ). What will happen to  $S_1, S_2$  and  $S$ ? What will happen to the other circles? You should be able to apply our old theorem about Miquel point.

**Problem 2.** No three of the points  $A, B, C, D$  are collinear. Prove that the angle between the circumcircles of triangles  $ABC$  and  $ABD$  is the same as the angle between the circumcircles of triangles  $ACD$  and  $BCD$ .

Hint: Perform a circular inversion in a circle with center  $A$ . What happens to the angles in question?

Problem 34.11

Problem 34.12

Problem 40.6

Problem 40.8

Problem 39.19

Problem 39.10

Problem 39.11

Hint: We can find the Euclidean center  $C$  of  $\zeta$  (how?). Consider the line  $OC$ . Explain why the  $P$ -center of  $\zeta$  is on  $OC$ . Now we may proceed in various ways.

**First approach:** It suffices to construct a circle  $T$  which is perpendicular to both  $\Gamma$  and  $\zeta$ . Explain why  $T$  will give a  $P$ -line which contains a  $P$ -diameter of  $\zeta$  (note: in any Hilbert plane a tangent at a point is perpendicular to the diameter from that point). Thus the point inside  $\zeta$  where  $T$  intersects the line  $OC$  is the  $P$ -center of  $\zeta$ . To construct  $T$ , note first that it is easy to construct a circle perpendicular

to a given line and a given circle. Then use appropriate inversion to reduce to this case.

**Second approach:** Use first appropriate inversion to reduce to the case when  $\zeta$  passes through  $O$ . Assuming that  $\zeta$  contains  $O$ , the idea from the first approach becomes even simpler. Let  $A$  be the second point of intersection of the line  $OC$  and  $\zeta$ . Find the inverse  $B$  of  $A$  in the circle  $\Gamma$ . Then  $B$  is outside of  $\Gamma$ . Draw a tangent to  $\Gamma$  from  $B$  and let  $D$  be the point of tangency. Prove that the circle with center at  $B$  and radius  $BD$  intersects the segment  $OA$  at the  $P$ -center of  $\zeta$ .

**Regardless of which approach you use, carefully explain how you do the appropriate inversions.**
